#### ABSTRACT

The International North Pacific Fisheries Commission (INPFC) has for many years sponsored an extensive program to tag salmon on the high seas. Much of its effort has focused on areas of interception in order to develop an understanding of salmon distribution and their pattern of movements. Chum salmon (Oncorhynchus keta) were tagged by INPFC member countries in the vicinity of the Alaska Peninsula and Eastern Aleutian Island chain from 1956 to 1966. Within this study area the greatest tagging effort occurred in the Pacific Ocean offshore of Umnak and Unalaska Islands. Recoveries from these tag releases were made throughout Western Alaska and along the Asian coast. Differences in arrival time could be discerned for the various chum salmon stocks being tagged. Summer run chum salmon from the Yukon River dominated the recoveries from May and early June releases. Norton Sound and Kuskokwim Bay chum salmon stocks were available for tagging throughout June. Bristol Bay chum salmon stocks appeared somewhat later with most recoveries made from the mid to late June releases. Yukon River fall run chum salmon were available for tagging in mid to late June. Tag recoveries of Kotzebue chum salmon were from the releases made mid June to early July. The percentage recovered by area could not be applied directly to determine the stock composition in the tagging area because of the failure to meet several important assumptions. Some of these assumptions were: (1) all stocks must be equally vulnerable to capture for tagging, (2) equal recovery rates must be applied in all areas, and (3) posttagging mortality and tag loss must be similar for all stocks.

KEY WORDS: chum salmon, *Oncorhynchus keta*, mark-recapture, interception, Alaska Peninsula, Aleutian Islands, Yukon River, Norton Sound, Kuskokwim Bay, Bristol Bay.

#### INTRODUCTION

Prior to the 1960's, chum salmon (Oncorhynchus keta) were used primarily for subsistence in Western Alaska mainly as food for sled dogs. Commercial fisheries for Western Alaska chum salmon expanded in the 1960's as fishing effort increased, processing capabilities improved, and new markets were established in Japan. The largest catches, north of Bristol Bay, have occurred in the Yukon River which supports both summer and fall chum stocks. A dramatic increase in the Yukon River commercial chum salmon catch took place in 1969 with a steady increase thereafter (Table 1). The largest Yukon River catch occurred in 1981 when nearly 1.7 million chum salmon were harvested. Combined catches in the Kotzebue-Norton Sound area have greatly increased, reaching 847,000 fish in 1981. The commercial chum salmon fishery in the Kuskokwim area expanded sharply in the 1970's and has produced an average catch of 395,000 chum salmon during the 1979-1983 period. In Bristol Bay, the commercial catch of chum salmon increased dramatically in 1976, staying near a million thereafter. The expanded Western Alaska chum fisheries are expected to fully utilize the resource in the 1980's. In general, the recent trend in all areas is for increased catches per unit of fishermen effort because of efficiency improvements while fishing time allowed per season by the management agency has decreased.

Additional pressure is exerted on Western Alaska chum salmon stocks by several interception fisheries. The Japanese mothership salmon fishery operates in the Bering Sea as well as in the North Pacific Ocean, harvesting 2-4 million chum salmon annually as well as other salmon species. The harvest may include Western Alaska chum salmon (Fredin et al. 1977). In addition, domestic fisheries along the Alaska Peninsula intercept non-local stocks especially in June. Most noteworthy are the South Unimak and Shumigan Island salmon fisheries which have been in operation since 1911. The combined average June chum salmon harvest from South Unimak and the Shumagin Islands has been 602,000 fish for the 1979-1983 period, an increase over the historic average of 249,000 for 1962-1978 (Table 1). Harvest guidelines for the South Unimak and Shumagin Island June sockeye salmon fisheries are currently established as 6.8% and 1.5%, respectively, of the latest projected Bristol Bay inshore sockeye salmon harvest. While most fishermen target upon the more valuable sockeye salmon, chum salmon are taken incidentally. In 1982, all time record catches of 875,000 and 140,000 chum salmon were made in the South Unimak and Shumagin Islands, respectively, in the month of June and again in 1983 large catches of 619,000 and 169,000 chum salmon were made (Table 1).

Increased harvest pressure in both the terminal and interception areas has placed additional allocation responsibility on fisheries managers. Considerable user group controversy could develop if the recent increased harvest levels in the interception fisheries are not coupled with the achievement of high harvest levels in terminal areas. The recent extremely large interception harvest on the Alaska Peninsula and the fact that average to poor chum salmon harvests were attained in some Western Alaska fisheries have focused considerable attention upon the South Unimak and Shumagin Islands salmon fisheries in 1982 and 1983. Two explanations have been proposed for the large interception catches. One is that the fishery is somehow targeting on chum salmon whose harvest is not limited by the guideline harvest levels set for sockeye salmon. An alternative explanation proposes that the chum salmon catch is purely incidental to the taking of sockeye salmon. The

Table 1. Commercial catch of chum salmon by area for Western Alaska, 1962-1983 (thousands of fish).

Does not include Canadian catches.

Includes catches made in the Kuskokwim River, Kuskokwim Bay, Quinhagak Bay and Goodnews Bay.

<sup>3</sup> From preliminary season summaries.

recent large sockeye salmon returns to Bristol Bay have greatly increased the allowable sockeye salmon catches and at the same time the incidental chum salmon catch has increased. Any future allocation scheme for chum salmon must be based on knowledge of the migration routes, timing differences, run strength, and final destination of the chum salmon passing through the interception fisheries.

Limited tagging studies have been conducted along the Alaska Peninsula and Aleutian Island chain (Gilbert and Rich 1925, Thorsteinson and Merrell 1964). These indicate that most of the sockeye and chum salmon available to the June South Unimak and Shumagin Island fisheries are of a non-local origin. Gilbert and Rich (1925) tagged chum salmon in early July off Unga Island which were recaptured over most of Western Alaska and Kamchatka. In contrast only local recoveries were made of chum salmon tagged during the second week of July off Unimak Island and the southwest shore of the Alaska Peninsula. The U.S. Fish and Wildlife Service conducted tagging studies in this area in 1961 which resulted in a similar recovery pattern (Thorsteinson and Merrell 1964). In 1961 tagging was conducted from 15 June to 14 July along Unimak Island and the southwest shore of the Alaska Peninsula. Recoveries were made from such distant areas as Norton Sound, the Yukon and Kuskokwim Rivers, and from nearby locations along the southern shore of the Alaska Peninsula (Table 2). Neither the time span over which tagging was conducted, nor the magnitude of the recoveries allows an analysis of differences in timing for the various stocks.

In addition to the previously mentioned tagging studies conducted by U.S. agencies, extensive research has been conducted under the coordination of an international organization. The International North Pacific Fisheries Commission (INPFC) was established by the International Convention for the High Seas Fisheries of the North Pacific in 1952. Participating nations include Canada, Japan, and the U.S. The three member countries have joined in major research programs to study salmon on the high seas. An extensive program has been underway for many years to tag salmon on the high seas and in areas of interception to develop an understanding of their distribution and pattern of movements. This report will present the results of chum salmon tagging studies in the vicinity of the southwest portion of the Alaska Peninsula and the eastern portion of the Aleutian Island chain.

#### INPFC TAGGING OF CHUM SALMON

Recovery information is available from high seas tagging conducted over the period 1956-1982 (Aro et al. 1971, Aro 1972, 1974, 1977, 1980; Meyer 1983). The tag release area of interest for this paper is a rectangle enclosing the southwest portion of the Alaska Peninsula and Eastern Aleutian Island chain (Figure 1). Of specific interest were tag recoveries from releases made adjacent to the Shumagin and Unimak Islands, however, the greatest tagging effort within the study area occurred in the Pacific Ocean between longitude 165°W and 170°W (Figure 2). Historically, release data have been available for each recovery and have consisted of a computer file listing of date, latitude, longitude, agency code, gear type used for capture, and tag number of release. Recovery data have consisted of date, latitude, longitude, and the recapture gear type. Biological data were also collected when possible at the time of release and recovery. This included species, length, age determination by examination of scales, sex, weight, and gonad weight.

Figure 1. Area of interest for distribution analysis of INPFC studies conducted, 1956-1966.

Figure 2. Areas of release for 279 tagged chum salmon recovered from INPFC sponsored studies of 1956-1966. Number of recoveries from each area is indicated. The area south of Unalaska and Umnak Islands include two recoveries made between the Kuskokwim and Yukon areas and one recovery each from the Strait of Georgia and Puget Sound.

See Appendix A for the description of area codes (Appendix Table 1) and the date and location of release and recovery for each chum salmon recovered from tagging conducted in the area adjacent to the Alaska Peninsula and Aleutian Island chain (Appendix Table 2).

Recoveries of chum salmon tagged in the study area were grouped as to the following recovery areas for purposes of this report:

Kotzebue Sound:

Includes recoveries along the shore and within systems draining into the area north of Cape Prince of Wales.

Norton Sound:

Includes recoveries from along the shore and within drainages from Cape Prince of Wales to Stuart Island.

Yukon River:

Includes recoveries in the Yukon River drainage.

Kuskokwim Bay:

Includes recoveries in the Kuskokwim Bay and River and

minor systems draining into the bay.

Bristol Bay:

Includes recoveries made from Cape Newenham to Ugashik Bay including all systems draining Bristol Bay within

this region.

North Alaska Peninsula: Includes recoveries made west of Ugashik Bay to Unimak

Pass on the north side of the peninsula.

South Alaska Peninsula:

Includes recoveries west of Shelikof Strait off Kodiak Island to Unimak Pass on the south side of the Alaska

Peninsula.

Asian Coast and Japan:

Includes recoveries made off the Western Pacific Ocean

and Bering Sea coasts or the drainages of Russia and

Japan.

High Seas:

Includes all recoveries made on the high seas and Aleutian

Island chain west of Unimak Pass.

The time period for analysis is limited to 1956-1966 because only in those years were substantial recoveries made from tagging conducted in the study area. Ninety percent of the recoveries were from tagging conducted by the Fisheries Research Institute (FRI) of the University of Washington under contract to the Bureau of Commercial Fisheries of the United States Fish and Wildlife Service. The remaining recoveries were of tags placed by the Fisheries Agency of Japan or in case of only two recoveries by the Fisheries Research Board of Canada. The primary method of capture used by FRI was a purse seine while longline gear was used by the Japanese Fisheries Agency. A total of 309 recoveries was made of which 90% occurred in the same year of tagging. Thirty tags were recovered in subsequent years implying that some immature fish were present in the study area. All discussion on the recovery distribution is based on recoveries made in the year of tagging unless otherwise specified.

#### RESULTS AND DISCUSSION

### Recovery Distribution from INPFC Tagging Studies

Recoveries of tagged chum salmon were grouped by the recovery areas previously defined to evaluate their distribution. The greatest number of recoveries were made along the Asian Coast and Japan (87) followed by the Yukon River (58) and Bristol Bay (56) areas (Table 3). A comparison of Asian and Alaskan recoveries indicates that 174 were Alaskan recoveries comprising 67% of the total (high seas recoveries were excluded). The recovery percentage by area varied greatly between years (Table 4) which is to be expected with the low number of recoveries in several years. When data from all years were pooled, three areas of recovery dominated with the Yukon River comprising 21%, Bristol Bay 20%, and the Asian Coast and Japan 32%. No recoveries were documented from the southern shore of the Alaska Peninsula and few along its northern shore. In addition, no recoveries were made along the Aleutian Island chain west of Unimak Pass.

It is of some interest to further delineate the release area for the tagged chum salmon recovered over the years 1956-1966. The release areas for the 275 recoveries of Table 3 are defined in Figure 2. We initially subdivided the study area shown in Figure 1 into six rectangular areas bordered by latitude lines 56°, 54°, and 52° N and longitudal lines 172°, 170°, 165°, and 160°W (Figure 2). Since recovered chum salmon were actually released in more restricted subareas for which specific locations are available release areas were bordered with dashed lines. The number of recoveries from each area is indicated in Figure 2. From Figure 2 it is apparent that most of the recoveries were made from tagging conducted just offshore of Umnak and Unalaska Islands. In contrast, few recoveries were made from tagging conducted near Unimak Island. Recovery distribution from the six rectangular release areas is presented in Table 5. Total release information was available for the six release areas but not for any finer delineation (dashed line areas of Figure 2). Yukon (58), Kuskokwim (23), and Bristol Bay (56) recoveries were made from releases in all areas east of 170°W (Table 5). In addition, Asian recoveries are notably missing from releases in the Unimak Island area (Table 5) even though most releases were made in June when Asian fish seem to pass through the area (Harris, personal communication). The extremely low sample size outside of the Unalaska area precludes any statistical statement about differences between release areas in their recovery distribution.

To better compare the recovery distribution with other studies, all years were pooled and viewed by time period for which total release numbers were available. Release information for May through July was available by period which was defined as three per month and consisted of at least 10 days. The seasonal duration of the INPFC tagging was far greater than in other studies (Gilbert and Rich 1925, Thorsteinson and Merrell 1964) ranging from 1 May through September. Timing differences for tag placement can be seen for chum salmon from the various recovery areas. Throughout the May release periods, the Yukon River was the predominant area of tag recovery (Tables 6 and 7), while in the first period of June nearly an equal number of recoveries were made in the Yukon River (13) and Asian Coast (12) areas. A similar level of recovery was made in Bristol Bay and the Asian Coast areas from tagging throughout the remainder of June. Tagging in the month of July and thereafter resulted in few recoveries (Tables 6 and 7).

Table 3. Number of INPFC chum salmon released and recovered from tagging studies conducted in the area adjacent to the Alaska Peninsula and Aleutian Island chain, 1956-1966. Only recoveries made in the year of tagging are presented.

<sup>2 = 11</sup> to 20th day of the month

<sup>3 &</sup>gt; 20th day of the month

Data were pooled by month for August and September.

Differences in time of release between recovery areas are discernible in Tables 6 and 7. From these data the mean date of release was calculated (Table 8) by first coding the release dates (CD), as 1 May = 1, 2 May = 2, 1 June = 32, ..., 31 July = 92, ...n for each recovery for a given area. The coded mean date of release (CMD) for that recovery area then became:

$$CMD = 1/n \sum_{i=1}^{n} CD_{i}$$

where the standard deviation (SD) was derived in a standard manner.

Table 8 presents the mean date of release for each recovery area in chronological order. The earliest mean (10 June) was observed for Yukon River recoveries (summer and fall runs combined) and the latest (24 June) in the Kotzebue area. It is important to note the magnitude of the standard deviations. Recovery areas which include a large region with many differently timed stocks would be expected to have a large variance. Therefore, one would expect the Asian Coast to have a large variance (12.4) as would the Yukon River (3.0) with its distinct summer and fall chum salmon runs (Table 8).

The comparatively large number of chum salmon recoveries from the Yukon River made it possible to separate early and late stocks. Summer chum salmon were defined for the purposes of this study as those which enter the Yukon River prior to 15 July and fall chum salmon as those which enter thereafter. Upriver recoveries were assigned as fall or summer chum salmon when possible by using information available on probable migration rate 32 to 48 km (20-30 mi) per day, time, and location of recovery. The recoveries designated as fall or summer chum salmon were then analyzed by period of release to determine if the mean date of release differs (Table 9) and if so which would be most vulnerable during June. These results indicate that summer run chum salmon were available for tagging earlier than the fall run with a 2 week difference in their mean date of release. Overall, it appeared that the fall chum salmon were more vulnerable to tagging in June where a good portion of the summer chum run may have passed through the area in May. With the exception of Yukon River summer stocks, the mean tagging date of all other Western Alaska chum salmon stocks appeared to fall well into June.

#### Stock Composition in the Release Area

Ideally, the percentage recovered by area would be applied directly to determine the actual stock composition at the time and place of release. Yet in doing so several strong assumptions must be fulfilled if the relative abundance of each stock at the time of tagging is to be based on its relative contribution to total recovery. Initially, during tagging all stocks must have been equally vulnerable to capture (Seber 1973). This requires that the number of fish tagged from each stock be in proportion to their relative abundance in a given area and time. A second assumption involves the loss of tagged fish. This would occur from natural mortality, tagging stress induced mortality, or tag loss. The analysis is not affected if tagged fish have a higher overall mortality than untagged fish as long as mortality is equal for stocks from all recovery areas. In addition, initial

<sup>3</sup> S.D. = Standard deviation of coded data, where 1 May = 1.

tag loss would most likely be shared equally amongst the different stocks being tagged and would not alter the relative frequency of recovery. It is likely however, that mortality and the shedding of tags are time dependent, often being modeled as an exponential decay process. Therefore, the greater the time between release and recovery the greater the mortality and tag loss in absolute numbers. This would infer that a recovery area distant to the release area, such as the Asian Coast and Kotzebue, would be under-represented in the total recoveries in comparison to nearby areas, having lost more fish through mortality or tag loss. In addition Asian chum salmon must pass through a massive high seas gill net fishery before reaching home streams. The high seas recoveries could be predominantly Asian origin fish representing a mortality source other stocks may escape. If different levels of mortality or tag loss are suffered by the tagged group the similarity between the recovery distribution and the stock composition in the release area is weakened.

One of the most important assumptions involves tag recovery and reporting. To determine relative stock strength from the recovery distribution, it must be assumed that all tags recovered were reported. In addition the recovery rate must be equal or known for all areas. For recovery rates to be equal it requires that similar percentages of each stock were surveyed for recoveries or that a tagged fish has a similar probability of recapture for each area. If recovery rates are unequal but known, adjustments can be made to the number of recoveries by area to make them comparable. If one area has a far superior tag recovery program it may provide a disproportionately high number of recoveries to the total. This assumption is most likely violated in this analysis as several features of the recovery areas indicate this. Japan may have an adequate recovery program yet information on U.S.S.R. harvests is difficult to obtain resulting in a very weak recovery program. In the U.S., tagging conducted by FRI was followed up by a tag recovery program and a reward system for returns, yet Western Alaska commercial chum salmon fisheries were not well developed during this period and most tag returns were obtained from subsistence fishermen and research projects conducted by federal and state agencies. In addition, the problem of overlooking tags in large catches would be greatest in the Bristol Bay commercial salmon fishery where chum salmon are far less abundant than sockeye salmon. Sockeye salmon virtually saturate the fishery during peak cycle years. How these factors interact is unknown though it would not be safe to assume a constant recovery rate for all areas and adjustments cannot be made as actual recovery rates are unknown.

In summary, the percentage recovered by area (Tables 4 and 7) cannot be applied directly to determine the stock composition in the tagging area. The assumptions previously discussed are unlikely to be met with the most obvious violation being that recovery rates were not constant or known in all areas.

#### SUMMARY

Chum salmon tagged in the vicinity of the Alaska Peninsula and Eastern Aleutian Island chain, 1956-1966, were recovered throughout Western Alaska and along the Asian Coast. Fish were tagged from May through July and differences in arrival times for the various chum salmon stocks were apparent from the differing mean dates of release. Summer run chum salmon from the Yukon River dominated the

recoveries from May and early June releases. Most recoveries from tagging throughout June were from the Bristol Bay and the Asian Coast. It was found for the Yukon River that the fall run chum salmon were available for tagging in mid to late June. The latest Western Alaska stock to be tagged was from Kotzebue with a 24 June mean date of release.

Stock composition at the time and place of tag release could not be based on the percentage recovered from each area. Recovery rates were not known to be equal. This then severely weakens any conclusions drawn in regards to the similarity between the release and recovery distributions. In addition, the presence of time dependent mortality or a tag shedding process would negate the comparison of recoveries in nearby and distant areas.

#### ACKNOWLEDGMENTS

Over 90% of the recoveries of tagged chum salmon discussed in this report were released during studies conducted by the Fisheries Research Institute (FRI) of the University of Washington while under contract to the Bureau of Commercial Fisheries of the U.S. Fish and Wildlife Service. Today, these data and the entire database from INPFC related studies are maintained at FRI. I wish to thank Colin Harris of FRI for providing release and recovery information and for reviewing the manuscript.

Location

Lat. = Degrees and minutes of north latitude, e.g., 15630E = 51°23' North.

Long. = Degrees and minutes of east or west longitude, e.g., 15630E=156°30' East.

- For area code description see Appendix Table 1.
- Recoveries are in the same year as release where the first two digits indicate the month and the last two digits indicate the day. The month is indicated as follows:
  - 00 = Recovery month and year unknown.
  - 01 = Recovery year is known but month and day are unknown.
  - 02-31 = Recovery month in year of tagging.

The day of recovery is indicated as follows:

- 00 = Day of month unknown.
- 01-31 = Day of month
  - 32 = Day and month unknown but year known.
